

Product Description

SALSA® MLPA® Probemixes

P251-C3 NB mix 1 & P252-D1 NB mix 2 & P253-D2 NB mix 3

To be used with the MLPA General Protocol.

Version P251-C3 / P252-D1 / P253-D2

For complete product history see page 15.

Catalogue numbers:

- **P251/P252/P253-025R:** SALSA® MLPA® Probemixes P251/P252/P253 NB mix 1, 2 & 3, 25 reactions.
- **P251/P252/P253-050R:** SALSA® MLPA® Probemixes P251/P252/P253 NB mix 1, 2 & 3, 50 reactions.
- **P251/P252/P253-100R:** SALSA® MLPA® Probemixes P251/P252/P253 NB mix 1, 2 & 3, 100 reactions.

SALSA® MLPA® Probemixes P251 NB mix 1, P252 NB mix 2 and P253 NB mix 3 (hereafter: P251 NB mix 1, P252 NB mix 2 and P253 NB mix 3) are to be used in combination with:

1. SALSA® MLPA® Reagent Kit (Cat. No: EK1-FAM, EK1-CY5, EK5-FAM, EK5-CY5, EK20-FAM),
2. Data analysis software Coffalyser.Net™ (Cat. No: n.a.)

Volumes and ingredients

Volumes			Ingredients
P251/2/3-025R	P251/2/3-050R	P251/2/3-100R	
40 µl	80 µl	160 µl	Synthetic oligonucleotides, oligonucleotides purified from bacteria, Tris-HCl, EDTA

The MLPA probemixes are not known to contain any harmful agents. Based on the concentrations present, none of the ingredients are hazardous as defined by the Hazard Communication Standard. A Safety Data Sheet (SDS) is not required for this product: none of the ingredients contain dangerous substances at concentrations requiring distribution of an SDS (as per Regulation (EC) No 1272/2008 [EU-GHS/CLP] and 1907/2006 [REACH] and amendments).

Storage and handling

Recommended storage conditions		
--------------------------------	---	---

A shelf life of until the expiry date is guaranteed, when stored in the original packaging under recommended conditions. For the exact expiry date, see the label on the vial. These products should not be exposed to more than 25 freeze-thaw cycles. Do not use these products if the packaging is damaged or opened. Leave chemicals in original containers. Waste material must be disposed of in accordance with the national and local regulations.

Certificate of Analysis

Information regarding storage conditions, quality tests, and a sample electropherogram from the current sales lots is available at www.mrcholland.com.

Precautions and warnings

For professional use only. Always consult the most recent product description AND the MLPA General Protocol before use: www.mrcholland.com. It is the responsibility of the user to be aware of the latest scientific knowledge of the application before drawing any conclusions from findings generated with these products.

General information

SALSA® MLPA® Probemixes P251/P252/P253 NB mix 1, 2 & 3 are research use only (RUO) assays for copy number determination of several chromosomal regions that frequently show copy number changes in neuroblastoma tumours.

Neuroblastoma (NB) is a relatively common paediatric cancer that usually occurs sporadically and frequently originates from one of the adrenal glands. NB is characterized by striking clinical heterogeneity, including cases that show spontaneous tumour regression. NB accounts up to 10% of all paediatric cancers. Several acquired genetic alterations such as amplification of the *MYCN* oncogene, deletions of chromosome bands 1p36 and 11q23 and unbalanced gains of 17q regions have been well-characterized and show correlation with tumour behaviour, including response to treatment. For review please see e.g. Ambros et al. (2009) and Ahmed et al. (2017).

These products are not CE/FDA registered for use in diagnostic procedures. The SALSA® MLPA® technique is covered by US patent 6,955,901 and corresponding patents outside the US. The purchase of this product includes a license to use only this amount of product solely for the purchaser's own use.

Probemix content

P251-C3 NB mix 1 contains 49 probes, including 36 probes for chromosomes 1, 3 and 11. P252-D1 NB mix 2 contains 49 probes, including 34 probes for chromosomes 2 (*MYCN* region) and 17. P253-D2 NB mix 3 contains 47 probes, including 33 probes for chromosomes 4, 7, 9, 12 and 14. In addition, 13 reference probes are included in P251, 15 in P252 and 14 in P253 that target relatively copy number stable regions in various cancer types including NB. However, it should be noted that NB karyotypes can harbour multiple numerical and structural aberrations, which can complicate interpretation of these reference probes. Partial probe sequences and the identity of the genes detected by the reference probes are available online (www.mrcholland.com).

The P251 probemix contains probes for chromosomes 1, 3 and 11:

- **1p36:** Deletion of the 1p36 region is present in 20-40% of NB patients and is often associated with *MYCN* amplification in ~70% of the cases (Huang and Weiss 2013). A probe for tumour suppressor gene *CHD5* at 1p36 is included.
- **3p21-p22:** 3p deletions are a hallmark of NB patients and appear to correlate with older age at diagnosis. This region contains various tumour suppressor genes, including *RASSF1* (Hoebeeck J et al. 2006; Van Roy et al. 2009).
- **11q:** Deletions of the 11q arm, and in particular 11q23, are common in NB patients and are associated with a higher disease stage and poor prognosis (Mlakar V et al. 2017)

The P252 probemix contains probes for chromosomes 2 and 17:

- **2p24:** Amplification of the proto-oncogene *MYCN* is found in 20-30% of all NBs and it correlates with poor prognosis. *MYCN* amplified tumours follow a very aggressive course and are associated with additional structural abnormalities – in particular with loss of 1p, 11q, and gain of 17q. *MYCN* amplification is often used for identification of high-risk NB patients, and is also one of the most commonly mutated genes in retinoblastoma (RB) after the *RB1* gene. *MYCN* is amplified in approximately 1-9 % of all RB tumors (Vempuluru VS et al. 2024). Additional probes for the nearby *NBAS*, *DDX1* and *ALK* genes are included.
- **2q33:** Loss of 2q33 has been reported in NBs and has been associated with loss of expression of *CASP8* (Takita J et al. 2001).
- **17p:** Gains of the 17p probes together with gains of the 17q probes would indicate complete chromosome 17 gains, in contrast to the frequent unbalanced 17q gains that are often associated with translocations. Three probes for *TP53* have been included although *TP53* mutations and deletions might be rare in NBs.
- **17q:** 17q gain is present in more than 50% of NB cases and is associated with a poor outcome. Several studies showed that the most common frequent sites of 17q translocations are 1p and 11q. Whole chromosome 17 gain is typically seen in near-triploid tumours with favourable prognosis (Mlakar V et al. 2024). Please note that triploidy of all chromosomes cannot be determined with these assays as only relative gains or losses are detected.

The P253 probemix contains probes for chromosomes 4, 7, 9, 12 and 14:

- Partial copy number alterations of chromosomes 4, 7, 9, 12 and 14 have been described in NBs. Probes for *CDKN2A* and *PTPRD* on chromosome 9 have been included as *CDKN2A* undergoes (often biallelic)

deletion in many cancer types, and the *PTPRD* gene has also been identified as a candidate tumour suppressor gene in NB (Carén H et al. 2008)

Each probemix contains nine quality control fragments generating amplification products between 64 and 105 nt: four DNA Quantity fragments (Q-fragments), two DNA Denaturation fragments (D-fragments), one Benchmark fragment, and one chromosome X and one chromosome Y-specific fragment (see table below). More information on how to interpret observations on these control fragments can be found in the MLPA General Protocol and online at www.mrcholland.com.

Length (nt)	Name
64-70-76-82	Q-fragments (only visible with <100 ng sample DNA)
88-96	D-fragments (low signal indicates incomplete denaturation)
92	Benchmark fragment
100	X-fragment (X chromosome specific)
105	Y-fragment (Y chromosome specific)

MLPA technique

The principles of the MLPA technique (Schouten et al. 2002) are described in the MLPA General Protocol (www.mrcholland.com). More information on the use of MLPA in tumour applications can be found in Hömig-Hölzel and Savola (2012).

MLPA technique validation

Internal validation using 16 different DNA samples from healthy individuals is required, in particular when using MLPA for the first time, or when changing the sample type or the sample handling procedure, DNA extraction method or instruments used. This validation experiment should result in a standard deviation ≤ 0.10 for all probes over the experiment.

Required specimens

Extracted DNA, which includes DNA derived from formalin-fixed, paraffin-embedded (FFPE) tissues, free from impurities known to affect MLPA reactions. MRC Holland has tested and can recommend the following extraction methods:

- QIAGEN Autopure LS (automated) and QIAamp DNA mini/midi/maxi kit (manual)
- Promega Wizard Genomic DNA Purification Kit (manual)
- Salting out (manual)

All samples tested, including reference DNA samples, should be derived from the same tissue type, handled using the same procedure, and prepared using the same DNA extraction method when possible. For more information please refer to the section on DNA sample treatment found in the MLPA General Protocol. More information on the use of FFPE tissue samples for MLPA can be found in Atanesyan et al. (2017).

Reference samples

A sufficient number (≥ 3) of different reference samples from unrelated individuals should be included in each MLPA experiment for data normalisation. Reference samples should be derived from healthy individuals without a history of cancer. More information regarding the selection and use of reference samples can be found in the MLPA General Protocol (www.mrcholland.com).

P252 competitor mix information

Samples with very high levels of *MYCN* amplification exhibit very high signals for the *MYCN* probes and low signals for other probes, making it difficult to analyse the latter. Therefore, the P252 probemix is shipped together with a vial of CM002 (P252 competitor mix). When a sample shows a very high level of *MYCN* amplification it can be retested with the competitor mix. This competitor mix contains oligonucleotides that can be included at the start of the MLPA reaction. Adding the competitors specifically reduces the signal of the eight *MYCN* region probes, making it possible to examine changes in other genes/chromosomal areas.

Instructions for use:

1. Denature 4 µl sample DNA by heating 5 minutes at 98°C.
2. Add 1.5 µl MLPA Buffer + 1.5 µl P252 probemix + 1 µl of P252 competitor mix.
3. Continue with the MLPA protocol starting with one minute incubation at 95°C and 16 hour incubation at 60°C followed by the ligation and PCR steps.

Positive control DNA samples

MRC Holland cannot provide positive DNA samples. Inclusion of a positive sample in each experiment is recommended. Coriell Institute (<https://catalog.coriell.org>) and Leibniz Institute DSMZ (<https://www.dsmz.de/>) have diverse collections of biological resources which may be used as positive control DNA samples in your MLPA experiments. Sample ID numbers listed in the table below from the Coriell Institute have been tested with P251-C3, P252-D1 and P253-D2 probemixes at MRC Holland and can be used as positive control samples to detect copy number alterations (CNAs) mentioned below. The quality of cell lines can change; therefore samples should be validated before use.

Sample name	Chromosomal position of CNA (hg18)*	Altered target genes in P251-C3 NB mix 1	Expected CNA
NA22977	1p36.33	<i>GABRD</i>	Heterozygous deletion
NA18827			
NA22995	1p36.32-p36.33	<i>GABRD, TP73</i>	Heterozygous deletion
NA22991

NA08763	7p15.1	<i>GHRHR</i>	Heterozygous deletion
NA12590	7q11.23	<i>ELN</i>	Heterozygous deletion
NA02819	9p13.3-p24.1	<i>PTPRD, CDKN2A, DNAI1</i>	Heterozygous duplication
NA14946	9p23-p24.1	<i>PTPRD</i>	Heterozygous deletion
	12p13.33	<i>ERC1</i>	Heterozygous duplication
NA13685	9q34.13	<i>POMT1, TSC1</i>	Heterozygous duplication
NA08035	12p11.21-p13.33	<i>ERC1, CDKN1B, PKP2</i>	Heterozygous duplication
NA10074	14q13.2-q32.12	<i>NFKBIA, ATL1, TGFB3, MOAP1</i>	Heterozygous duplication
NA09888	14q22.1	<i>ATL1</i>	Heterozygous deletion

* Indicated chromosomal bands accommodate genes targeted by MLPA probes, however, the whole extent of CNAs present in these cell lines cannot be determined by the P251-C3/P252-D1/P253-D2 NB mix 1, 2 & 3 probemixes.

Data analysis

Coffalyser.Net should be used for data analysis in combination with the appropriate lot-specific Coffalyser sheet. For both, the latest version should be used. Coffalyser.Net is freely downloadable at www.mrcholland.com. Use of other non-proprietary software may lead to inconclusive or false results. For more details on MLPA quality control and data analysis, including normalisation, see the Coffalyser.Net Reference Manual.

Interpretation of results

The standard deviation of each individual probe over all the reference samples should be ≤ 0.10 . When this criterion is fulfilled, the following cut-off values for the final ratio (FR) of the probes can be used to interpret MLPA results for autosomal chromosomes or pseudo-autosomal regions:

Copy number status	Final ratio (FR)
Normal	$0.80 < FR < 1.20$
Homozygous deletion	$FR = 0$
Heterozygous deletion	$0.40 < FR < 0.65$
Heterozygous duplication/gain	$1.30 < FR < 1.65$
Heterozygous triplication/homozygous duplication/gain	$1.75 < FR < 2.15$
Ambiguous copy number	All other values

Note: The term “dosage quotient”, used in older product description versions, has been replaced by “final ratio” to become consistent with the terminology of Coffalyser.Net (Calculations, cut-offs and interpretation remain unchanged.) Please note that Coffalyser.Net also shows arbitrary borders as part of the statistical analysis of results obtained in an experiment. As such, arbitrary borders are different from the final ratio cut-off values shown here above.

Please note that these above mentioned final ratios are only valid for germline testing. Final ratios are affected both by percentage of tumour cells and by possible subclonality.

- Arranging probes according to chromosomal location facilitates interpretation of the results and may reveal more subtle changes such as those observed in subclonal cases.
- False positive results: Please note that abnormalities detected by a single probe (or multiple consecutive probes) still have a considerable chance of being a false positive result. Sequence changes (e.g. single nucleotide variants (SNVs), point mutations) in the target sequence detected by a probe can be one cause. Incomplete DNA denaturation (e.g. due to salt contamination in the DNA sample) can also lead to a decreased probe signal, in particular for probes located in or near a GC-rich region. The use of an additional purification step or an alternative DNA extraction method may resolve such cases. Additionally, contamination of DNA samples with cDNA or PCR amplicons of individual exons can lead to an increased probe signal (Varga et al. 2012). Analysis of an independently collected secondary DNA sample can exclude these kinds of contamination artefacts.
- Normal copy number variation in healthy individuals is described in the database of genomic variants: <http://dgv.tcag.ca/dgv/app/home>. Users should always consult the latest update of the database and scientific literature when interpreting their findings.
- Not all abnormalities detected by MLPA are pathogenic. In some genes, intragenic deletions are known that result in very mild or no disease (as described for *DMD* by Schwartz et al. 2007). For many genes, more than one transcript variant exists. Copy number changes of exons that are not present in all transcript variants may not have clinical significance. Duplications that include the first or last exon of a gene (e.g. exons 1-3) might not result in inactivation of that gene copy.
- Copy number changes detected by reference probes are unlikely to have any relation to the condition tested for.
- False results can be obtained if one or more peaks are off-scale. For example, a duplication of one or more exons can be obscured when peaks are off-scale, resulting in a false negative result. The risk on off-scale peaks is higher when probemixes are used that contain a relatively low number of probes. Coffalyser.Net software warns for off-scale peaks while other software does not. If one or more peaks are off-scale, rerun the PCR products using either: a lower injection voltage or a shorter injection time, or a reduced amount of sample by diluting PCR products.

P251/P252/P253 specific notes

- In samples from tumour tissues, reference probes are more prone to have deviating copy number results as compared to blood-derived germline samples. When regions targeted by reference probes are affected by CNAs, it can help to turn the slope correction off in Coffalyser.Net analysis to get the correct copy number interpretation on the target region.
- Probes in chromosomes 1, 2, 3, 4, 7, 9, 11, 12, 14 and 17 are included in the probemixes to help determine the extent of a deletion/duplication. CNAs of single probes might not always be related to the condition tested.

Limitations of the procedure

- Small (point) mutations and structural rearrangements occurring in NB will not be detected by P251-C3, P252-D1 and P253-D2 NB mix 1, 2 & 3.
- MLPA cannot detect any changes that lie outside the target sequence of the probes and will not detect copy number neutral inversions or translocations. Even when MLPA did not detect any aberrations, the possibility remains that biological changes in that gene or chromosomal region do exist but remain undetected.
- Sequence changes (e.g. SNVs, point mutations) in the target sequence detected by a probe can cause false positive results. Mutations/SNVs (even when >20 nt from the probe ligation site) can reduce the probe signal by preventing ligation of the probe oligonucleotides or by destabilising the binding of a probe oligonucleotide to the sample DNA.
- MLPA analysis on tumour samples provides information on the *average* situation in the cells from which the DNA sample was purified. Gains or losses of genomic regions or genes may not be detected if the percentage of tumour cells is low. In addition, subclonality of the aberration affects the final ratio of the corresponding probe. Furthermore, there is always a possibility that one or more reference probes *do* show a CNA in a patient sample, especially in solid tumours with more chaotic karyotypes.

Confirmation of results

Copy number changes detected by only a single probe always require confirmation by another method. An apparent deletion detected by a single probe can be due to e.g. a mutation/polymorphism that prevents ligation or destabilises the binding of probe oligonucleotides to the DNA sample. Sequence analysis can establish whether mutations or polymorphisms are present in the probe target sequence. The finding of a heterozygous mutation or polymorphism in sequence data indicates that two different alleles of the sequence are present in the sample DNA and that a false positive MLPA result was obtained.

Copy number changes detected by more than one consecutive probe should be confirmed by another independent technique such as long range PCR, qPCR, array CGH or Southern blotting, whenever possible. Deletions/duplications of more than 50 kb in length can often be confirmed by FISH.

COSMIC mutation database

<http://cancer.sanger.ac.uk/cosmic>. We strongly encourage users to deposit positive results in the COSMIC Database. Recommendations for the nomenclature to describe deletions/duplications of one or more exons can be found on <http://varnomen.hgvs.org/>.

Please report false-positive results due to SNVs and unusual results to MRC Holland: info@mrcholland.com.

Table 1. P251-C3 NB mix 1

* New in version C3.

¥ Changed in version C3. Minor alteration, no change in sequence detected.

« Probe located in or near a GC-rich region. A low signal can be caused by salt contamination in the DNA sample leading to incomplete DNA denaturation, especially of GC-rich regions.

± SNP rs55707108 could influence the probe signal at 266 nt. In case of apparent deletions, it is recommended to sequence the region targeted by this probe.

This probe's specificity relies on a single nucleotide difference compared to a related gene or pseudogene. As a result, an apparent duplication of only this probe can be the result of a non-significant single nucleotide sequence change in the related gene or pseudogene.

« Probe located in or near a GC-rich region. A low signal can be caused by salt contamination in the DNA sample leading to incomplete DNA denaturation, especially of GC-rich regions.

± SNP rs554374026 could influence the probe signal at 283 nt. In case of apparent deletions, it is recommended to sequence the region targeted by this probe.

+ An article by Costa and Seuánez (2018) reports that the 6p region can be gained in neuroblastoma samples. These two 6p reference probes can be removed from the normalisation calculations when necessary by adjusting the Coffalyser sheet.

These probes' specificity relies on a single nucleotide difference compared to a related gene or pseudogene. As a result, an apparent duplication of only these probes can be the result of a non-significant single nucleotide sequence change in the related gene or pseudogene.

* New in version D2.

¥ Changed in version D2. Minor alteration, no change in sequence detected.

« Probe located in or near a GC-rich region. A low signal can be caused by salt contamination in the DNA sample leading to incomplete DNA denaturation, especially of GC-rich regions.

± SNVs rs17290162 and rs550975729 could influence the probe signal at 303 nt and 232 nt, respectively. In case of apparent deletions, it is recommended to sequence the region targeted by the probe.

These probes' specificity relies on a single nucleotide difference compared to a related gene or pseudogene. As a result, an apparent duplication of only these probes can be the result of a non-significant single nucleotide sequence change in the related gene or pseudogene.

The identity of the genes detected by the reference probes and their complete probe sequences are available at www.mrcholland.com. Please notify us of any mistakes: info@mrcholland.com.

The probe lengths in the tables above may vary slightly depending on the capillary electrophoresis machine settings. Please see the most up-to-date Coffalyser sheet for exact probe lengths obtained at MRC Holland.

SNVs located in the target sequence of a probe can influence probe hybridisation and/or probe ligation. Please note: not all known SNVs are mentioned in the tables above. Single probe aberration(s) must be confirmed by another method.

« Probe located in or near a GC-rich region. A low signal can be caused by salt contamination in the DNA sample leading to incomplete DNA denaturation, especially of GC-rich regions.

± SNV rs554374026 could influence the probe signal at 283 nt. In case of apparent deletions, it is recommended to sequence the region targeted by this probe.

These probes' specificity relies on a single nucleotide difference compared to a related gene or pseudogene. As a result, an apparent duplication of only these probes can be the result of a non-significant single nucleotide sequence change in the related gene or pseudogene.

* New in version D2.

¥ Changed in version D2. Minor alteration, no change in sequence detected.

« Probe located in or near a GC-rich region. A low signal can be caused by salt contamination in the DNA sample leading to incomplete DNA denaturation, especially of GC-rich regions.

± SNVs rs17290162 and rs550975729 could influence the probe signal at 303 nt and 232 nt, respectively. In case of apparent deletions, it is recommended to sequence the region targeted by this probe.

These probes' specificity relies on a single nucleotide difference compared to a related gene or pseudogene. As a result, an apparent duplication of only these probes can be the result of a non-significant single nucleotide sequence change in the related gene or pseudogene.

SNVs located in the target sequence of a probe can influence probe hybridisation and/or probe ligation. Please note: not all known SNVs are mentioned in the tables above. Single probe aberration(s) must be confirmed by another method.

P251 product history	
<i>Version</i>	<i>Modification</i>
C3	One probe on chromosome 1 and four reference probes have been replaced, and one probe has a change in length but not in the sequence detected.
C2	Three new reference probes have been added and two have been replaced, and multiple probes have a change in length but not in the sequence detected.
C1	Two new LM01 specific probes and new QDX fragments (QDX2) have been included.
B1	Several probes have been replaced and extra X- and Y-control fragments have been added. In addition, new reference probes have been included.
A1	First release.

P252 product history	
<i>Version</i>	<i>Modification</i>
D1	Five new reference probes have been added and two have been replaced, and multiple probes have a change in length but not in the sequence detected.
C1	One probe for 2p telomere and an extra ALK specific probe have been added.
B1	Several probes have been replaced and extra X- and Y-control fragments have been added. In addition, new reference probes have been included.
A1	First release.

P253 product history	
<i>Version</i>	<i>Modification</i>
D2	Two target and five reference probes have been replaced, and multiple probes have a change in length but not in the sequence detected.
D1	Four new reference probes have been added and two have been replaced, and multiple probes have a change in length but not in the sequence detected.
C1	One NFKBIA specific probe has been replaced.
B1	Several probes have been replaced and extra X- and Y-control fragments have been added. In addition, new reference probes have been included.
A1	First release.

Implemented changes in the product description
<i>Version C3/D1/D2-01 – 16 June 2025(05P)</i> - Product description rewritten and adapted to a new template. - Product description adapted to new product versions (version number changed for P251 and P253, changes in Table 1, 3, 4 and 6). - New references added. - Information about positive control DNA samples updated. - Warnings about denaturation-sensitivity removed for several probes. - Warnings added to Tables 1 – 3 about probe specificity relying on a single nucleotide difference between target gene and related gene or pseudogene. <i>Version C2/D1/D1-04 – 31 January 2023 (04P)</i> - Corrections made in the positive sample table on page 4: NA10985 has a heterozygous deletion of <i>VHL</i>, instead of a duplication and one typo corrected. <i>Version C2/D1/D1-03 – 30 June 2022 (04P)</i> - Product description rewritten and adapted to a new template. - For uniformity, the chromosomal locations and bands in this document are now all based on hg18 (NCBI36). - New warnings for SNPs influencing probe signals added and salt warnings adjusted based on newest data in Tables 1 to 6.

- Gene name of *ST5* updated to *DENND2B*.
- Information about positive control DNA samples added.
- New references added.
- Related probemixes section updated.
